

Boolean Function Representation Binary Decision Diagram (BDD)

□ A graphical representation of Boolean function

- BDD is a Shannon cofactor tree:
 - $f = v f_v + v' f_{\bar{v}}$ (Shannon expansion)
 - vertices represent decision nodes (i.e. multiplexers) controlled by variables
 - leafs are constants "0" and "1"
 - two children of a vertex of f represent two subfunctions f_v and $f_{\bar{v}}$
- Variable ordering restriction and reduction rules make (ROBDD) representation **canonical**

33

Boolean Function Representation BDD – Canonicalization

- General idea:
 - instead of exploring sub-cases by enumerating them in time, try to store sub-cases in memory
 - **KEY:** two hashing mechanisms:
 - unique table: find identical sub-cases and avoid replication
 - computed table: reduce redundant computation of sub-cases
- Represent logic functions as graphs (DAGs):
 - many logic functions can be represented compactly - usually better than SOPs
- Can be made **canonical** (ROBDD)
 - Shift the effort in a Boolean reasoning engine from SAT algorithm to data representation
- Many logic operations can be performed efficiently on BDD's:
 - usually linear in size of input BDDs
 - tautology checking and complement operation are constant time
- BDD size critically depends on variable ordering

34

Boolean Function Representation BDD – Canonicalization

- Directed acyclic graph (DAG)
 - one root node, two terminal-nodes, 0 and 1
 - each node has two children and is controlled by a variable
- Shannon cofactor tree, except **reduced** and **ordered** (ROBDD)
 - **Ordered**:
 - cofactor variables (splitting variables) in the **same order along all paths**

$$x_{i_1} < x_{i_2} < x_{i_3} < \dots < x_{i_n}$$
 - **Reduced**:
 - any node with two identical children is removed
 - two nodes with isomorphic BDD's are merged
 These two rules make any node in an ROBDD represent a distinct logic function

35

Boolean Function Representation BDD

□ Example

Same function with two different variable orders

36

Boolean Function Representation

BDD – Canonicity of ROBDD

- Three components make ROBDD canonical (Bryant 1986):
 - unique nodes for constant “0” and “1”
 - identical order of case-splitting variables along each paths
 - a hash table that ensures
 - $(\text{node}(f_v) = \text{node}(g_v)) \wedge (\text{node}(f_{v'}) = \text{node}(g_{v'})) \Rightarrow \text{node}(f) = \text{node}(g)$
- and provides recursive argument that $\text{node}(f)$ is unique when using the unique hash-table

37

Boolean Function Representation

BDD – Onset Counting

$F = b' + a'c' = ab' + a'cb' + a'c'$ (all paths to the 1 node)

- By tracing all paths to the 1 node, we get a **cover** of **pairwise disjoint** cubes
- BDD does **not** explicitly enumerate all paths; rather it represents paths by a graph whose size is measured by its nodes
 - A DAG can represent an **exponential number of paths** with a linear number of nodes
- BDDs can be used to efficiently represent sets
 - interpret elements of the onset as elements of the set
 - f is called the **characteristic function** of that set

38

Boolean Function Representation

BDD – ITE Operator

- Each BDD node can be written as a triplet: $f = \text{ite}(v, g, h) = vg + v'h$, where $g = f_v$ and $h = f_{\bar{v}}$, meaning **if v then g else h**

(v is top variable of f)

39

Boolean Function Representation

BDD – ITE Operator

- $\text{ite}(f, g, h) = fg + f'h$
 - ITE operator can implement any two variable logic function. There are 16 such functions corresponding to all subsets of vertices of B^2 :

Table	Subset	Expression	Equivalent Form
0000	0	0	0
0001	AND(f, g)	$f g$	$\text{ite}(f, g, 0)$
0010	$f > g$	$f g'$	$\text{ite}(f, g', 0)$
0011	f	f	f
0100	$f < g$	$f'g$	$\text{ite}(f, 0, g)$
0101	g	g	g
0110	XOR(f, g)	$f \oplus g$	$\text{ite}(f, g', g)$
0111	OR(f, g)	$f + g$	$\text{ite}(f, 1, g)$
1000	NOR(f, g)	$(f + g)'$	$\text{ite}(f, 0, g')$
1001	XNOR(f, g)	$f \oplus g'$	$\text{ite}(f, g, g')$
1010	NOT(g)	g'	$\text{ite}(g, 0, 1)$
1011	$f \geq g$	$f + g'$	$\text{ite}(f, 1, g')$
1100	NOT(f)	f'	$\text{ite}(f, 0, 1)$
1101	$f \leq g$	$f' + g$	$\text{ite}(f, g, 1)$
1110	NAND(f, g)	$(f g)'$	$\text{ite}(f, g', 1)$
1111	1	1	1

40

Boolean Function Representation

BDD – ITE Operator

□ Recursive operation of ITE

$$\begin{aligned} \text{Ite}(f,g,h) &= f g + f' h \\ &= v (f g + f' h)_v + v' (f g + f' h)_{v'} \\ &= v (f_v g_v + f'_v h_v) + v' (f_{v'} g_{v'} + f'_{v'} h_{v'}) \\ &= \text{ite}(v, \text{ite}(f_v, g_v, h_v), \text{ite}(f_{v'}, g_{v'}, h_{v'})) \end{aligned}$$

- Let v be the top-most variable of BDDs f, g, h

41

Boolean Function Representation

BDD – ITE Operator

□ Recursive computation of ITE

```
Algorithm ITE(f, g, h)
  if(f == 1) return g
  if(f == 0) return h
  if(g == h) return g

  if((p = HASH_LOOKUP_COMPUTED_TABLE(f,g,h)) return p
  v = TOP_VARIABLE(f, g, h) // top variable from f,g,h
  fn = ITE(f_v, g_v, h_v) // recursive calls
  gn = ITE(f_{v'}, g_{v'}, h_{v'})
  if(fn == gn) return gn // reduction
  if(!(p = HASH_LOOKUP_UNIQUE_TABLE(v,fn,gn)) {
    p = CREATE_NODE(v,fn,gn) // and insert into UNIQUE_TABLE
  }
  INSERT_COMPUTED_TABLE(p, HASH_KEY{f,g,h})
  return p
}
```

42

Boolean Function Representation

BDD – ITE Operator

Example

$$\begin{aligned}
 I &= \text{ite}(F, G, H) \\
 &= \text{ite}(a, \text{ite}(F_a, G_a, H_a), \text{ite}(F_{\bar{a}}, G_{\bar{a}}, H_{\bar{a}})) \\
 &= \text{ite}(a, \text{ite}(1, C, H), \text{ite}(B, 0, H)) \\
 &= \text{ite}(a, C, \text{ite}(b, \text{ite}(B_b, 0_b, H_b), \text{ite}(B_{\bar{b}}, 0_{\bar{b}}, H_{\bar{b}}))) \\
 &= \text{ite}(a, C, \text{ite}(b, \text{ite}(1, 0, 1), \text{ite}(0, 0, D))) \\
 &= \text{ite}(a, C, \text{ite}(b, 0, D)) \\
 &= \text{ite}(a, C, J)
 \end{aligned}$$

Check: $F = a + b$
 $G = ac$
 $H = b + d$
 $\text{ite}(F, G, H) = (a + b)(ac) + a'b'(b + d) = ac + a'b'd$

43

Boolean Function Representation

BDD – ITE Operator

Tautology checking using ITE

```

Algorithm ITE_CONSTANT(f,g,h) { // returns 0,1, or NC
  if(TRIVIAL_CASE(f,g,h) return result (0,1, or NC)
  if((res = HASH_LOOKUP_COMPUTED_TABLE(f,g,h))) return res
  v = TOP_VARIABLE(f,g,h)
  i = ITE_CONSTANT(f_v,g_v,h_v)
  if(i == NC) {
    INSERT_COMPUTED_TABLE(NC, HASH_KEY{f,g,h}) // special table!!
    return NC
  }
  e = ITE_CONSTANT(f_v,g_v,h_v)
  if(e == NC) {
    INSERT_COMPUTED_TABLE(NC, HASH_KEY{f,g,h})
    return NC
  }
  if(e != i) {
    INSERT_COMPUTED_TABLE(NC, HASH_KEY{f,g,h})
    return NC
  }
  INSERT_COMPUTED_TABLE(e, HASH_KEY{f,g,h})
  return i;
}
    
```

44

Boolean Function Representation

BDD – ITE Operator

□ Composition using ITE

- **Compose** is an important operation, e.g. for building the BDD of a circuit backwards, $\text{Compose}(F, v, G) : F(v, x) \rightarrow F(G(x), x)$, means substitute $v = G(x)$

```
Algorithm COMPOSE(F,v,G) {  
  if(TOP_VARIABLE(F) > v) return F // F does not depend on v  
  if(TOP_VARIABLE(F) == v) return ITE(G,F1,F0)  
  i = COMPOSE(F1,v,G)  
  e = COMPOSE(F0,v,G)  
  return ITE(TOP_VARIABLE(F),i,e)  
}
```

Note:

1. F1 and F0 are the 1-child and 0-child of F, respectively
2. G, i, e are not functions of v
3. If TOP_VARIABLE of F is v, then $\text{ITE}(G, F1, F0)$ does the replacement of v by G

45

Boolean Function Representation

BDD – Implementation Issues

Unique table:

- avoids duplication of existing nodes
 - Hash-Table: $\text{hash-function}(\text{key}) = \text{value}$
 - identical to the use of a hash-table in AND/INVERTER circuits

Computed table:

- avoids re-computation of existing results

46

Boolean Function Representation

BDD – Implementation Issues

Unique table

- Before a node $ite(v, g, h)$ is added to BDD database, it is looked up in the "unique-table". If it is there, then existing pointer to node is used to represent the logic function. Otherwise, a new node is added to the unique-table and the new pointer returned.
- Thus a **strong canonical form** is maintained. The node for $f = ite(v, g, h)$ exists **iff** $ite(v, g, h)$ is in the unique-table. There is only one pointer for $ite(v, g, h)$ and that is the address to the unique-table entry.
- Unique-table allows single multi-rooted DAG to represent all users' functions

47

Boolean Function Representation

BDD – Implementation Issues

Computed table

- Keep a record of (F, G, H) triplets already computed by the ITE operator
 - software cache ("cache" table)
 - simply hash-table without collision chain (lossy cache)

48

Boolean Function Representation

BDD – Implementation Issues

□ Use of computed table

- BDD packages often use optimized implementations for special operations
 - e.g. `ITE_Constant` (check whether the result would be a constant) `AND_Exist` (AND operation with existential quantification)
- All operations need a cache for decent performance
 - local cache
 - for one operation only - cache will be thrown away after operation is finished (e.g. `AND_Exist`)
 - special cache for each operation
 - does not need to store operation type
 - shared cache for all operations
 - better memory handling
 - needs to store operation type

49

Boolean Function Representation

BDD – Implementation Issues

□ Complemented edges

- Combine inverted functions by using complemented edge
 - similar to AIG
 - reduces memory requirements
 - more importantly, makes operations NOT, ITE more efficient

two different DAGs

only one DAG using complement pointer

50

Boolean Function Representation

BDD – Implementation Issues

Complemented edges

- To maintain strong canonical form, need to resolve 4 equivalences:

- Solution:** Always choose the ones on **left**, i.e. the “then” leg must have **no** complemented edge.

51

Boolean Function Representation

BDD – Implementation Issues

Complemented edges

Standard triples:

$$ite(F, F, G) \Rightarrow ite(F, 1, G)$$

$$ite(F, G, F) \Rightarrow ite(F, G, 0)$$

$$ite(F, G, \neg F) \Rightarrow ite(F, G, 1)$$

$$ite(F, \neg F, G) \Rightarrow ite(F, 0, G)$$

To resolve equivalences: $ite(F, 1, G) \equiv ite(G, 1, F)$

$$ite(F, 0, G) \equiv ite(\neg G, 1, \neg F)$$

$$ite(F, G, 0) \equiv ite(G, F, 0)$$

$$ite(F, G, 1) \equiv ite(\neg G, \neg F, 1)$$

$$ite(F, G, \neg G) \equiv ite(G, F, \neg F)$$

To maximize matches on computed table:

- First argument is chosen with smallest top variable.
- Break ties with smallest address pointer. (breaks PORTABILITY!)

Triples:

$$ite(F, G, H) \equiv ite(\neg F, H, G) \equiv \neg ite(F, \neg G, \neg H) \equiv \neg ite(\neg F, \neg H, \neg G)$$

Choose the one such that the first and second argument of *ite* should not be complemented edges (i.e. the first one above)

52

Boolean Function Representation

BDD – Implementation Issues

- Variable ordering – static
 - variable ordering is computed up-front based on the problem structure
 - works well for many practical combinational functions
 - general scheme: control variables first
 - DFS order is good for most cases
 - works bad for unstructured problems
 - e.g. using BDDs to represent arbitrary sets
 - lots of ordering algorithms
 - simulated annealing, genetic algorithms
 - give better results but extremely costly

53

Boolean Function Representation

BDD – Implementation Issues

- Variable ordering – dynamic
 - Changes the order in the middle of BDD applications
 - must keep same global order
 - Problem: External pointers reference internal nodes!

External reference pointers attached
to application data structures

BDD Implementation:

54

Boolean Function Representation

BDD – Implementation Issues

□ Variable ordering – dynamic

Theorem (Friedman):

Permuting any top part of the variable order has no effect on the nodes labeled by variables in the bottom part.

Permuting any bottom part of the variable order has no effect on the nodes labeled by variables in the top part.

- Trick: Two adjacent variable layers can be exchanged by keeping the original memory locations for the nodes

55

Boolean Function Representation

BDD – Implementation Issues

□ Variable ordering – dynamic

■ BDD sifting:

- shift each BDD variable to the top and then to the bottom and see which position had minimal number of BDD nodes
- efficient if separate hash-table for each variable
- can stop if lower bound on size is worse than the best found so far
- shortcut: two layers can be swapped very cheaply if there is no interaction between them
- expensive operation

■ grouping of BDD variables:

- for many applications, grouping variables gives better ordering
 - e.g. current state and next state variables in state traversal
- grouping variables for sifting

56

Boolean Function Representation

BDD – Implementation Issues

□ Garbage collection

- Important to free and reuse memory of unused BDD nodes including
 - those explicitly freed by an external `bdd_free` operation
 - those temporary created during BDD operations
- Two mechanisms to check whether a BDD is not referenced:
 - **Reference counter** at each node
 - increment whenever node gets one more referenced
 - decrement when node gets de-referenced
 - take care of counter-overflow
 - **Mark and sweep** algorithm
 - does not need counter
 - first pass, mark all BDDs that are referenced
 - second pass, free the BDDs that are not marked
 - need additional handle layer for external references

57

Boolean Function Representation

BDD – Implementation Issues

□ Garbage collection

- Timing is crucial because garbage collection is expensive
 - immediately when node gets freed
 - bad because dead nodes get often reincarnated in subsequent operations
 - regular garbage collections based on statistics obtained during BDD operations
- Computed-table must be cleared since not used in reference mechanism
- Improving memory locality and therefore cache behavior

58

Boolean Function Representation

BDD – Variants

- MDD: Multi-valued DD
 - have more than two branches
 - can be implemented using a regular BDD package with binary encoding
 - the binary variables for one MV variable do not have to stay together and thus potentially better ordering
- ADD: (Algebraic BDDs) MTBDD
 - multi-terminal BDDs
 - decision tree is binary
 - multiple leaves, including real numbers, sets or arbitrary objects
 - efficient for matrix computations and other non-integer applications
- FDD: Free-order BDD
 - variable ordering differs
 - not canonical anymore
- ...

59

Boolean Function Representation

BDD – Variants

- Zero suppressed BDD (ZDD)
 - ZBDDs were invented by Minato to efficiently represent **sparse** sets. They have turned out to be **useful** in implicit methods for representing primes (**which usually are a sparse subset of all cubes**).
 - Different reduction rules:
 - **BDD**: eliminate all nodes where **then** edge and **else** edge point to the same node.
 - **ZBDD**: eliminate all nodes where the **then** node points to 0. Connect incoming edges to **else** node.
 - **For both**: share equivalent nodes.

60

Boolean Function Representation

BDD – Variants

Theorem: ZBDDs are canonical given a variable ordering and the support set

Example

BDD

ZBDD if support is x_1, x_2

ZBDD if support is x_1, x_2, x_3

BDD

ZBDD if support is x_1, x_2, x_3

61

Boolean Function Representation

Summary

- Sum of products
 - Good for circuit synthesis
- Product of sums
 - Good for Boolean reasoning
- Boolean network
 - Generic network
 - Good for multi-level circuit synthesis
 - And-inverter graph
 - Good for Boolean reasoning
- Binary decision diagram
 - Good for Boolean reasoning

62

Boolean Reasoning

Reading:

Logic Synthesis in a Nutshell

Section 2

most of the following slides are by
courtesy of Andreas Kuehlmann

63

Boolean Reasoning Satisfiability (SAT)

- Boolean reasoning engines need:
 - a data structure to represent problem instances
 - a decision procedure to decide about SAT or UNSAT
- Fundamental tradeoff
 - canonical data structure (e.g. truth table, ROBDD)
 - data structure uniquely represents function
 - decision procedure is trivial (e.g., just pointer comparison)
 - Problem: size of data structure is in general exponential
 - non-canonical data structure (e.g. AIG, CNF)
 - systematic search for satisfying assignment
 - size of data structure is linear
 - Problem: decision may take an exponential amount of time

64

Boolean Reasoning

SAT

□ Basic SAT algorithms:

- branch and bound algorithm
 - branching on the assignments of primary inputs only or those of all variables
 - E.g. PODEM vs. D-algorithms in ATPG

□ Basic data structures:

- circuits or CNF formulas
- SAT on circuits is **identical** to the justification part in ATPG
 - 1st half of ATPG: justification
 - find an input assignment that forces an internal signal to a required value
 - 2nd half of ATPG: propagation
 - make a signal change at an internal signal observable at some outputs (can be easily formulated as SAT over CNF formulas)

65

Boolean Reasoning

SAT vs. Tautology

□ SAT:

- find a truth assignment to the inputs making a given Boolean formula true
- NP-complete

□ Tautology:

- find a truth assignment to the inputs making a given Boolean formula false
- coNP-complete

□ SAT and Tautology are dual to each other

- checking SAT on formula φ = checking Tautology on formula $\neg\varphi$, and vice versa

66

Boolean Reasoning

SAT – AIG-based Decision Procedure

- General Davis-Putnam procedure
 - search for **consistent** assignment to entire cone of requested vertex in AIG by systematically trying all combinations (**may be partial**)
 - keep a queue of vertices that remain to be justified
 - pick **decision vertex** from the queue and case split on possible assignments
 - for each case
 - propagate as many implications as possible
 - generate more vertices to be justified
 - if conflicting assignment encountered, undo all implications and backtrack
 - recur to next vertex from queue

67

Boolean Reasoning

SAT – AIG-based Decision Procedure

- General Davis-Putnam procedure

```
Algorithm SAT(Edge p) {
    queue = INIT_QUEUE(p)
    if(!IMPLY(p)) return FALSE
    return JUSTIFY(queue)
}
```

```
Algorithm JUSTIFY(queue) {
    if(Queue_EMPTY(queue)) return TRUE
    mark = ASSIGNMENT_MARK()
    v = Queue_NEXT(queue) // decision vertex
    if(IMPLY(NOT(v))) {
        if(JUSTIFY(queue)) return TRUE
    } // conflict
    UNDO_ASSIGNMENTS(mark)
    if(IMPLY(v)) {
        if(JUSTIFY(queue)) return TRUE
    } // conflict
    UNDO_ASSIGNMENTS(mark)
    return FALSE
}
```

68

Boolean Reasoning

SAT – AIG-based Decision Procedure

Example

SAT(NOT(9))??

Queue

Assignments

1st case for 9:

conflict !

- undo all assignments
- backtrack

69

Boolean Reasoning

SAT – AIG-based Decision Procedure

Example (cont'd)

2nd case for 9:

Note:

vertex 7 is justified
by 8->5->7

Queue

Assignments

1st case for 5:

Solution cube: 1 = x, 2 = 0, 3 = 0

70

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Implication

- Fast implication procedure is key for efficient SAT solver!
 - don't move into circuit parts that are not sensitized to current SAT problem
 - detect conflicts as early as possible
- Table lookup implementation (27 cases):
 - No-implication cases:

71

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Implication (cont'd)

- Table lookup implementation (27 cases):
 - Implication cases:

- Conflict cases:

- Split case:

72

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Case split

- Different heuristics work well for particular problem classes
- Often **depth-first heuristic** is good because it generates conflicts quickly
- Mixture of **depth-first** and **breadth-first** schedule
- Other heuristics:
 - pick the vertex with the **largest fanout**
 - count the **polarities** of the fanout **separately** and pick the vertex with the highest count in either polarity
 - run a **full implication** phase on all outstanding case splits and count the number of implications one would get
 - pick vertices that are involved in **small cut** of the circuit

73

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Learning

- Learning is the process of adding “shortcuts” to the circuit structure that avoids case splits
 - static learning:
 - global implications are learned
 - dynamic learning:
 - learned implications only hold in current part of the search tree
- Learned implications are stores as additional network
- Example (cont'd)
 - 1st case for vertex 9 lead to conflict
 - If we were to try the same assignment again (e.g. for the next SAT call), we would get the same conflict => merge vertex 7 with zero-vertex

- if rehashing is invoked
vertex 9 is simplified and
and merged with vertex 8

74

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – static

- Implications that can be learned structurally from the circuit
 - Add learned structure as circuit

Use hash table to find structure in circuit:

```

Algorithm CREATE_AND(p1,p2) {
    . . . // create new vertex p
    if((p'=HASH_LOOKUP(p1,NOT(p2))) {
        LEARN(((p=0)&(p'=0)) => (p1=0))
    }
    if((p'=HASH_LOOKUP(NOT(p1),p2)) {
        LEARN(((p=0)&(p'=0)) => (p2=0))
    }
}
    
```

75

Boolean Reasoning

SAT – AIG-based Decision Procedure

Example (cont'd)

2nd case for 9 (original):

Queue

Assignments

2nd case for 9 (with static learning):

Solution cube: 1 = x, 2 = x, 3 = 0

76

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – static

- Other learning based on contra-positive:
if $(P \Rightarrow Q)$, then $(\neg Q \Rightarrow \neg P)$

```

foreach vertex v {
  mark = ASSIGNMENT_MARK()
  IMPLY(v)
  LEARN_IMPLICATIONS(v)
  UNDO_ASSIGNMENTS(mark)
  IMPLY(NOT(v))
  LEARN_IMPLICATIONS(NOT(v))
  UNDO_ASSIGNMENTS(mark)
}
    
```

- Problem: learned implications are far too many
 - solution: restrict learning to non-trivial implications and filter redundant implications

$$((x = 0) \Rightarrow (y = 1)) \Rightarrow ((y = 0) \Rightarrow (x = 1))$$

77

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – static and recursive

- Compute the set of all implications for both case splits on level i
 - Static learning of constants, equivalences
- Intersect both split cases to learn for level $i-1$

$$((x = 1) \Rightarrow (y = 1) \wedge (x = 0) \Rightarrow (y = 1)) \Rightarrow (y = 1)$$

- Apply learning recursively until all case splits exhausted
 - recursive learning is complete but very expensive in practice for levels $> 2, 3$
 - restrict learning level to fixed number \rightarrow becomes incomplete

78

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Learning – static and recursive

```
Algorithm RECURSIVE_LEARN(int level) {
  if(v = PICK_SPLITTING_VERTEX()) {
    mark = ASSIGNMENT_MARK()
    IMPLY(v)
    IMPL1 = RECURSIVE_LEARN(level+1)
    UNDO_ASSIGNMENTS(mark)
    IMPLY(NOT(v))
    IMPL0 = RECURSIVE_LEARN(level+1)
    UNDO_ASSIGNMENTS(mark)
    return IMPL1  $\cap$  IMPL0
  }
  else { // completely justified
    return IMPLICATIONS
  }
}
```

79

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Learning – dynamic

- Learn implications in a sub-tree of searching
 - cannot simply add permanent structure because not globally valid
 - add and remove learned structure (expensive)
 - add branching condition to the learned implication
 - of no use unless we prune the condition (conflict learning)
 - use implication and assignment mechanism to assign and undo assigns
 - e.g., dynamic recursive learning with fixed recursion level
 - Dynamic learning of equivalence relations (Stalmarck procedure)
 - learn equivalence relations by dynamically rewriting the formula

80

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – dynamic

- Efficient implementation of **dynamic recursive learning** with level 1:

- consider both sub-cases in parallel

- use 27-valued logic in the IMPLY routine

(level0-value, level1-choice1, level1-choice2)

({0,1,x}, {0,1,x}, {0,1,x})

- automatically set learned values for level0 if both level1 choices agree, e.g.,

81

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – conflict-based (c.f. structure-based)

- Idea:** Learn the situation under which a particular conflict occurred and assert it to 0
 - IMPLY will use this “shortcut” to detect similar conflict earlier

- Definition:** An **implication graph** is a directed Graph $I(G',E)$, $G' \subseteq G$ are the gates of C with assigned values $v_g \neq \text{unknown}$, $E \subseteq G' \times G'$ are the edges, where each edge $(g_i, g_j) \in E$ reflects an implication for which an assignment of gate g_i leads to the assignment of gate g_j .

Circuit:

Implication graph:

82

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – conflict-based

- The roots (w/o fanin-edges) of the implication graph correspond to the decision vertices, the leaves correspond to the implication frontier

- There is a strict implication order in the graph from the roots to the leaves
 - We can completely cut the graph at any point and identify value assignments to the cut vertices, we result in identical implications toward the leaves
- $$C_1 \Rightarrow C_2 \Rightarrow \dots \Rightarrow C_{n-1} \Rightarrow C_n \quad (C_1: \text{decision vertices})$$

83

Boolean Reasoning

SAT – AIG-based Decision Procedure

Learning – conflict-based

- If an implication leads to a conflict, any cut assignment in the implication graph between the decision vertices and the conflict will result in the same conflict!

$$(C_i \Rightarrow \text{Conflict}) \Rightarrow (\text{NOT}(\text{Conflict}) \Rightarrow \text{NOT}(C_i))$$

- We can learn the complement of the cut assignment as circuit
 - find minimal cut in the implication graph I (costs less to learn)
 - find dominator vertex if exists
 - restrict size of cuts to be learned, otherwise exponential blow-up

84

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Non-chronological backtracking

- If we learned only cuts on decision vertices, only the decision vertices that are in the support of the conflict are needed

- The conflict is **fully symmetric** with respect to the unrelated decision vertices!!
 - Learning the conflict would prevent checking the symmetric parts again
 - BUT: It is too expensive to learn all conflicts (any cut)

85

Boolean Reasoning

SAT – AIG-based Decision Procedure

□ Non-chronological backtracking

- We can still avoid exploring symmetric parts of the decision tree by tracking the decision support vertices of a conflict
 - If no conflict of the first choice on a decision vertex depends on that vertex, the other choice will result in symmetric conflicts and their evaluation can be skipped!
- By tracking the implications of the decision vertices we can skip decision levels during backtrack

86

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ CNF

- Product-of-Sums (POS) representation of Boolean function
- Describes solution using a set of constraints
 - very handy in many applications because new constraints can be simply added to the list of existing constraints
 - very common in AI community
- Example
$$\varphi = (a+b'+c) (a'+b+c) (a+b'+c') (a+b+c)$$
- SAT on CNF (POS) \Leftrightarrow TAUTOLOGY on DNF (SOP)

87

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Circuit to CNF conversion

- Encountered often in practical applications
- Naive conversion from circuit to CNF:
 - multiply out expressions of circuit until two level structure
 - Example: $y = x_1 \oplus x_2 \oplus x_2 \oplus \dots \oplus x_n$ (parity function)
 - circuit size is **linear in the number of variables**

- generated chess-board Karnaugh map
 - CNF (or DNF) formula has 2^{n-1} terms (**exponential in the # vars**)
- Better approach:
 - introduce one variable per circuit vertex
 - formulate the circuit as a conjunction of constraints imposed on the vertex values by the gates
 - uses more variables but size of formula is linear in the size of the circuit

88

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Circuit to CNF conversion

■ Example

□ Single gate

□ Connected gates

89

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ DPLL procedure

```

Algorithm DPLL() {
  while ChooseNextAssignment() {
    while Deduce() == CONFLICT {
      blevel = AnalyzeConflict();
      if (blevel < 0) return UNSATISFIABLE;
      else Backtrack(blevel);
    }
  }
  return SATISFIABLE;
}

```

ChooseNextAssignment picks next decision variable and assignment
 Deduce does Boolean Constraint Propagation (implications)
 AnalyzeConflict backprocesses from conflict and produces learnt-clause
 Backtrack undoes assignments

91

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Implication

- Implications in a CNF formula are caused by **unit clauses**

- A unit clause is a CNF term for which all variables except one are assigned
 - the value of that clause can be implied immediately

□ Example

$$(a + \neg b + c) \quad (a=0) \quad (b=1) \Rightarrow (c=1)$$

92

Boolean Reasoning

SAT – CNF-based Decision Procedure

Implication

Example

Non-implication cases:

93

Boolean Reasoning

SAT – CNF-based Decision Procedure

Implication

Example (cont'd)

Implication cases:

94

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ DPLL (w/ implication)

- 1 $(a + b + c)$
- 2 $(a + b + \neg c)$
- 3 $(\neg a + b + \neg c)$
- 4 $(a + c + d)$
- 5 $(\neg a + c + d)$
- 6 $(\neg a + c + \neg d)$
- 7 $(\neg b + \neg c + \neg d)$
- 8 $(\neg b + \neg c + d)$

Source: Karem A. Sakallah, Univ. of Michigan

95

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Conflict-based learning

- Important detail for cut selection:
 - During implication processing, record decision level for each implication
 - At conflict, select earliest cut such that **exactly one node of the implication graph lies on current decision level**
 - Either decision variable itself
 - Or UIP (“unique implication point”) that represents a dominator node for current decision level in conflict graph
- By selecting such cut, implication processing will automatically flip decision variable (or UIP variable) to its complementary value

96

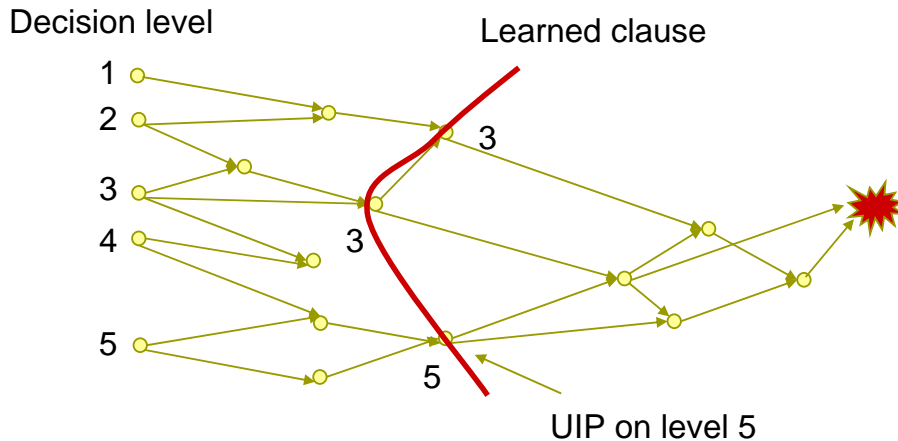

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Conflict-based learning

■ UIP detection

- Store with each implication the decision level, and a time stamp (integer that is incremented after each decision)
 - UIP on decision level l has the property that all following implications towards the conflict have a larger time stamp
 - When back processing from conflict, put all implications that are to be processed on heap, keeping the one with smallest time stamp on top
 - If during processing there is only one variable on current decision level on heap then that variable must be a UIP

97

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ DPLL (conflict-based learning)

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Implementation issues

- Clauses are stores in arrays
- Track change-sensitive clauses (two-literal watching)
 - all literals but one assigned -> **implication**
 - all literals but two assigned -> clause is **sensitive to a change** of either literal
 - all other clauses are insensitive and do not need to be observed
- Learning:
 - learned implications are added to the CNF formula as additional clauses
 - limit the size of the clause
 - limit the “lifetime” of a clause, will be removed after some time
- Non-chronological back-tracking
 - similar to circuit case

99

Boolean Reasoning

SAT – CNF-based Decision Procedure

□ Implementation issues (cont'd)

- Random restarts:
 - stop after a given number of backtracks
 - start search again with modified ordering heuristic
 - keep learned structures !
 - very effective for satisfiable formulas, often also effective for unsat formulas
- Learning of equivalence relations:
 - if $(a \Rightarrow b) \wedge (b \Rightarrow a)$, then $(a = b)$
 - very powerful for formal equivalence checking
- Incremental SAT solving
 - solving similar CNF formulas in a row
 - share learned clauses
