

Division

□ Definition:

G is an **algebraic factor** of F if there exists an algebraic expression H such that $F = GH$ (using algebraic multiplication)

□ Definition:

G is an **Boolean factor** of F if there exists an expression H such that $F = GH$ (using Boolean multiplication)

□ Example

■ $f = ac + ad + bc + bd$

□ $(a+b)$ is an algebraic factor of f since $f = (a+b)(c+d)$

■ $f = -ab + ac + bc$

□ $(a+b)$ is a Boolean factor of f since $f = (a+b)(-a+c)$

41

Why Algebraic Methods?

□ Algebraic methods provide fast algorithms for various operations

■ Treat logic functions as polynomials

■ Fast algorithms for polynomials exist

■ Lost of optimality but results are still good

■ Can iterate and interleave with Boolean operations

□ In specific instances, slight extensions are available to include Boolean methods

42

Weak Division

- **Weak division** is a specific example of algebraic division
- Definition: Given two algebraic expressions F and G , a division is called a **weak division** if
 1. it is **algebraic** and
 2. R has **as few cubes as possible**
 - The **quotient** H resulting from weak division is denoted by F/G
- Theorem: Given expressions F and G , H and R generated by weak division are unique

43

Weak Division

```
ALGORITHM WEAK_DIV(F,G) {
  // G = {g1,g2,...}, F = {f1,f2,...} are sets of cubes
  foreach gi {
    vgi = ∅
    foreach fj {
      if(fj contains all literals of gi) {
        vij = fj - literals of gi
        vgi = vgi ∪ vij
      }
    }
  }
  H = ∑i vgi
  R = F - GH
  return (H,R);
}
```

44

Weak Division

□ Example

$$F = ace + ade + bc + bd + be + a'b + ab$$

$$G = ae + b$$

$$V^{ae} = c + d$$

$$V^b = c + d + e + a' + a$$

$$H = c + d = F/G$$

$$H = \bigcap V^{g_i}$$

$$R = be + a'b + ab$$

$$R = F \setminus GH$$

$$F = (ae + b)(c + d) + be + a'b + ab$$

45

Weak Division

□ We use **filters** to prevent trying a division

■ G is not an algebraic divisor of F if

□ G contains a literal not in F,

□ G has more terms than F,

□ For any literal, its count in G exceeds that in F, or

□ F is in the transitive fanin of G

46

Weak Division

- Weak_Div provides a method to divide an expression for a given divisor
- How do we find a “good” divisor?
 - Restrict to algebraic divisors
 - Generalize to Boolean divisors
- Problem:
Given a set of functions $\{ F_i \}$, find **common weak (algebraic) divisors**.

47

Divisor Identification

Primary Divisor

- Definition:
An expression is **cube-free** if no cube divides the expression evenly (i.e. there is no literal that is common to all the cubes)
 - “ab+c” is cube-free
 - “ab+ac” and “abc” are not cube-free
 - Note: A cube-free expression **must** have more than one cube
- Definition:
The **primary divisors** of an expression F are the set of expressions
$$D(F) = \{ F/c \mid c \text{ is a cube} \}$$
Note that F/c is the quotient of a weak division

48

Divisor Identification Kernel and Co-Kernel

□ Definition:

The **kernels** of an expression F are the set of expressions

$$K(F) = \{G \mid G \in D(F) \text{ and } G \text{ is cube-free}\}$$

- In other words, the kernels of an expression F are the **cube-free primary divisors** of F

□ Definition:

A cube c used to obtain the kernel $K = F/c$ is called a **co-kernel** of K

- $C(F)$ is used to denote the **set of co-kernels** of F

49

Divisor Identification Kernel and Co-Kernel

□ Example

$$\begin{aligned}x &= adf + aef + bdf + bef + cdf + cef + g \\ &= (a + b + c)(d + e)f + g\end{aligned}$$

kernels

$a+b+c$

$d+e$

$(a+b+c)(d+e)f+g$

co-kernels

df, ef

af, bf, cf

1

50

Divisor Identification

Kernel and Kernel Intersection

□ Fundamental Theorem

If two expressions F and G have the property that

$\forall k_F \in K(F), \forall k_G \in K(G) \rightarrow |k_G \cap k_F| \leq 1$
(k_G and k_F have at most one term in common),

then F and G have **no common** algebraic divisors with **more than one cube**

■ Important:

If we “kernel” all functions and there are no nontrivial intersections, then the only common algebraic divisors left are **single cube divisors**

51

Divisor Identification

Kernel Level

□ Definition:

A kernel is of **level 0** (K^0) if it contains no kernels except itself

A kernel is of **level n** or less (K^n) if it contains at least one kernel of level (n-1) or less, but no kernels (except itself) of level n or greater

- $K^n(F)$ is the set of kernels of level n or less
- $K^0(F) \subset K^1(F) \subset K^2(F) \subset \dots \subset K^n(F) \subset K(F)$
- level-n kernels = $K^n(F) \setminus K^{n-1}(F)$

□ Example:

$$F = (a + b(c + d))(e + g)$$

$$k_1 = a + b(c + d) \in K^1 \\ \notin K^0 \implies \text{level-1}$$

$$k_2 = c + d \in K^0$$

$$k_3 = e + g \in K^0$$

52

Divisor Identification Kerneling Algorithm

```
Algorithm KERNEL(j, G) {  
  R =  $\emptyset$   
  if(CUBE_FREE(G)) R = {G}  
  for(i=j+1,...,n) {  
    if( $l_i$  appears only in one term)           continue  
    if( $\exists k \leq i, l_k \in$  all cubes of  $G/l_i$ ) continue  
    R = R  $\cup$  KERNEL(i, MAKE_CUBE_FREE( $G/l_i$ ))  
  }  
  return R  
}
```

MAKE_CUBE_FREE(F) removes algebraic cube factor from F

53

Divisor Identification Kerneling Algorithm

□ **KERNEL**(0, F) returns all the kernels of F

□ Note:

- The test “($\exists k \leq i, l_k \in$ all cubes of G/l_i)” in the kerneling algorithm is a **major** efficiency factor. It also guarantees that no co-kernel is tried more than once
- Can be used to generate all co-kernels

54

Divisor Identification Kerneling Algorithm

□ Example

$$F = abcd + abce + adfg + aefg + adbe + acdef + beg$$

55

Divisor Identification Kerneling Algorithm

□ Example

co-kernels

1
a
ab
abc
abd
abe
ac
acd

kernels

$a((bc + fg)(d + e) + de(b + cf)) + beg$
 $(bc + fg)(d + e) + de(b + cf)$
 $c(d+e) + de$
 $d + e$
 $c + e$
 $c + d$
 $b(d + e) + def$
 $b + ef$

Note: $F/bc = ad + ae = a(d + e)$

56

Factor

```
Algorithm FACTOR(F) {  
  if(F has no factor) return F  
  // e.g. if |F|=1, or F is an OR of single literals  
  // or of no literal appears more than once  
  D      = CHOOSE_DIVISOR(F)  
  (Q,R) = DIVIDE(F,D)  
  return FACTOR(Q)×FACTOR(D) + FACTOR(R) //recur  
}
```

- different heuristics can be applied for **CHOOSE_DIVISOR**
- different **DIVIDE** routines may be applied (algebraic division, Boolean division)

57

Factor

□ Example:

$$F = abc + abd + ae + af + g$$

$$D = c + d$$

$$Q = ab$$

$$P = ab(c + d) + ae + af + g$$

$$O = ab(c + d) + a(e + f) + g$$

Notation:

F = original function

D = divisor

Q = quotient

P = partial factored form

O = final factored form by

FACTOR restricting to

algebraic operations only

■ Problem 1:

O is not optimal since not maximally factored and can be further factored to “a(b(c + d) + e + f) + g”

- It occurs when quotient Q is a single cube, and some of the literals of Q also appear in the remainder R

58

Factor

□ To solve Problem 1

■ Check if the quotient Q is not a single cube, then done

■ Else, pick a literal l_1 in Q which occurs most frequently in cubes of F . Divide F by l_1 to obtain a new divisor D_1 .

Now, F has a new partial factored form

$$(l_1)(D_1) + (R_1)$$

and literal l_1 does not appear in R_1 .

□ **Note:** The new divisor D_1 contains the original D as a divisor because l_1 is a literal of Q . When recursively factoring D_1 , D can be discovered again.

59

Factor

□ Example:

$$F = ace + ade + bce + bde + cf + df$$

$$D = a + b$$

$$Q = ce + de$$

$$P = (ce + de)(a + b) + (c + d)f$$

$$O = e(c + d)(a + b) + (c + d)f$$

Notation:

F = original function

D = divisor

Q = quotient

P = partial factored form

O = final factored form by

FACTOR restricting to

algebraic operations only

■ Problem 2:

O is not maximally factored because “ $(c + d)$ ” is common to both products “ $e(c + d)(a + b)$ ” and “ $(c + d)f$ ”

□ The final factored form should have been “ $(c+d)(e(a + b) + f)$ ”

60

Factor

□ To solve Problem 2

■ Essentially, we reverse D and Q!!

- Make Q **cube-free** to get Q_1
- Obtain a new divisor D_1 by dividing F by Q_1
- If D_1 is cube-free, the partial factored form is $F = (Q_1)(D_1) + R_1$, and can recursively factor Q_1 , D_1 , and R_1
- If D_1 is not cube-free, let $D_1 = cD_2$ and $D_3 = Q_1D_2$. We have the partial factoring $F = cD_3 + R_1$. Now recursively factor D_3 and R_1 .

61

Factor

```
Algorithm GFACTOR(F, DIVISOR, DIVIDE) { // good factor
  D = DIVISOR(F)
  if(D = 0) return F
  Q = DIVIDE(F,D)
  if (|Q| = 1) return LF(F, Q, DIVISOR, DIVIDE)
  Q = MAKE_CUBE_FREE(Q)
  (D, R) = DIVIDE(F,Q)
  if (CUBE_FREE(D)) {
    Q = GFACTOR(Q, DIVISOR, DIVIDE)
    D = GFACTOR(D, DIVISOR, DIVIDE)
    R = GFACTOR(R, DIVISOR, DIVIDE)
    return Q × D + R
  }
  else {
    C = COMMON_CUBE(D) // common cube factor
    return LF(F, C, DIVISOR, DIVIDE)
  }
}
```

62

Factor

```
Algorithm LF(F, C, DIVISOR, DIVIDE) { // literal
  factor
  L = BEST_LITERAL(F, C) //L ∈ C most frequent in F
  (Q, R) = DIVIDE(F, L)
  C = COMMON_CUBE(Q) // largest one
  Q = CUBE_FREE(Q)
  Q = GFACTOR(Q, DIVISOR, DIVIDE)
  R = GFACTOR(R, DIVISOR, DIVIDE)
  return L × C × Q + R
}
```

63

Factor

- ❑ Various kinds of factoring can be obtained by choosing different forms of **DIVISOR** and **DIVIDE**
- ❑ **CHOOSE_DIVISOR**:
 - LITERAL** - chooses most frequent literal
 - QUICK_DIVISOR** - chooses the first level-0 kernel
 - BEST_DIVISOR** - chooses the best kernel
- ❑ **DIVIDE**:
 - Algebraic Division
 - Boolean Division

64

Factor

□ Example

$$x = ac + ad + ae + ag + bc + bd + be + bf + ce + cf + df + dg$$

LITERAL_FACTOR:

$$x = a(c + d + e + g) + b(c + d + e + f) + c(e + f) + d(f + g)$$

QUICK_FACTOR:

$$x = g(a + d) + (a + b)(c + d + e) + c(e + f) + f(b + d)$$

GOOD_FACTOR:

$$(c + d + e)(a + b) + f(b + c + d) + g(a + d) + ce$$

65

Factor

- QUICK_FACTOR uses GFACTOR, first level-0 kernel DIVISOR, and WEAK_DIV

□ Example

$$x = ae + afg + afh + bce + bcfg + bcfh + bde + bdfg + bcfh$$

$$D = c + d \quad \text{---- level-0 kernel (first found)}$$

$$Q = x/D = b(e + f(g + h)) \quad \text{---- weak division}$$

$$Q = e + f(g + h) \quad \text{---- make cube-free}$$

$$(D, R) = \text{WEAK_DIV}(x, Q) \quad \text{---- second division}$$

$$D = a + b(c + d)$$

$$x = QD + R \quad R = 0$$

$$x = (e + f(g + h)) (a + b(c + d))$$

66

Decomposition

- Decomposition is the same as factoring **except**:
 - divisors are added as **new** nodes in the network.
 - the new nodes may **fan out** elsewhere in the network in both positive and **negative** phases

```
Algorithm DECOMP( $f_i$ ) {  
   $k = \mathbf{CHOOSE\_KERNEL}(f_i)$   
  if ( $k == 0$ ) return  
   $f_{m+j} = k$  // create new node  $m + j$   
   $f_i = (f_i/k)y_{m+j} + (f_i/k')y'_{m+j} + r$  // change node  $i$  using  
  // new node for kernel  
  
  DECOMP( $f_i$ )  
  DECOMP( $f_{m+j}$ )  
}
```

Similar to factoring, we can define
QUICK_DECOMP: pick a level 0 kernel and improve it
GOOD_DECOMP: pick the best kernel

67

Substitution

- **Idea**: An existing node in a network may be a useful divisor in another node. If so, no loss in using it (unless delay is a factor).
- Algebraic substitution consists of the process of algebraically dividing the function f_i at node i in the network by the function f_j (or by f'_j) at node j . During substitution, if f_j is an algebraic divisor of f_i , then f_i is transformed into
 $f_i = qy_j + r$ (or $f_i = q_1y_j + q_0y'_j + r$)
- In practice, this is tried for each node pair of the network. n nodes in the network $\Rightarrow O(n^2)$ divisions.

68

Extraction

- **Recall:** Extraction operation identifies **common** sub-expressions and restructures a Boolean network
 - Combine **decomposition** and **substitution** to provide an effective extraction algorithm

Algorithm **EXTRACT**

```
foreach node n {  
    DECOMP(n) // decompose all network nodes  
}  
foreach node n {  
    RESUB(n) // resubstitute using existing nodes  
}  
ELIMINATE_NODES_WITH_SMALL_VALUE  
}
```

69

Extraction

- **Kernel Extraction:**
 1. Find **all** kernels of all functions
 2. **Choose** kernel intersection with best “value”
 3. **Create** new node with this as function
 4. Algebraically **substitute** new node everywhere
 5. Repeat 1,2,3,4 until best value \leq threshold

70

Extraction

□ Example

$$f_1 = ab(c(d + e) + f + g) + h$$

$$f_2 = ai(c(d + e) + f + j) + k$$

(only level-0 kernels used in this example)

1. Extraction:

$$K^0(f_1) = K^0(f_2) = \{d + e\}$$

$$K^0(f_1) \cap K^0(f_2) = \{d + e\}$$

$$l = d + e$$

$$f_1 = ab(cl + f + g) + h$$

$$f_2 = ai(cl + f + j) + k$$

2. Extraction:

$$K^0(f_1) = \{cl + f + g\}; K^0(f_2) = \{cl + f + j\}$$

$$K^0(f_1) \cap K^0(f_2) = cl + f$$

$$m = cl + f$$

$$f_1 = ab(m + g) + h$$

$$f_2 = ai(m + j) + k$$

No kernel intersections anymore!!

3. Cube extraction:

$$n = am$$

$$f_1 = b(n + ag) + h$$

$$f_2 = i(n + aj) + k$$

71

Extraction Rectangle Covering

□ Alternative method for extraction

□ Build co-kernel cube matrix $M = R^T C$

- rows correspond to co-kernels of individual functions

- columns correspond to individual cubes of kernel

- m_{ij} = cubes of functions

- $m_{ij} = 0$ if cube not there

□ Rectangle covering:

- identify sub-matrix $M^* = R^{*T} C^*$, where $R^* \subseteq R$, $C^* \subseteq C$, and $m^*_{ij} \neq 0$

- construct divisor d corresponding to M^* as new node

- extract d from all functions

72

Extraction Rectangle Covering

□ Example

$$F = af + bf + ag + cg + ade + bde + cde$$

$$G = af + bf + ace + bce$$

$$H = ade + cde$$

Kernels/Co-kernels:

$$F: (de+f+g)/a$$

$$(de + f)/b$$

$$(a+b+c)/de$$

$$(a + b)/f$$

$$(de+g)/c$$

$$(a+c)/g$$

$$G: (ce+f)/\{a,b\}$$

$$(a+b)/\{f,ce\}$$

$$H: (a+c)/de$$

| | | <i>a</i> | <i>b</i> | <i>c</i> | <i>ce</i> | <i>de</i> | <i>f</i> | <i>g</i> |
|--------------|-----------|------------|------------|------------|------------|------------|-----------|-----------|
| <i>F</i> | <i>a</i> | | | | | <i>ade</i> | <i>af</i> | <i>ag</i> |

73

Extraction Rectangle Covering

□ Example (cont'd)

$$F = af + bf + ag + cg + ade + bde + cde$$

$$G = af + bf + ace + bce$$

$$H = ade + cde$$

■ Pick sub-matrix *M'*

■ Extract new expression *X*

$$F = fx + ag + cg + dex + cde$$

$$G = fx + cex$$

$$H = ade + cde$$

$$X = a + b$$

■ Update *M*

| | | <i>a</i> | <i>b</i> | <i>c</i> | <i>ce</i> | <i>de</i> | <i>f</i> | <i>g</i> |
|--------------|-----------|------------|------------|------------|------------|------------|-----------|-----------|
| <i>F</i> | <i>a</i> | | | | | <i>ade</i> | <i>af</i> | <i>ag</i> |
| <i>F</i> | <i>b</i> | | | | | <i>bde</i> | <i>bf</i> | |
| <i>F</i> | <i>de</i> | <i>ade</i> | <i>bde</i> | <i>cde</i> | | | | |
| <i>F</i> | <i>f</i> | <i>af</i> | <i>bf</i> | | | | | |

| <i>G</i> | <i>ce</i> | <i>ace</i> | <i>bce</i> | | | | | |
| <i>G</i> | <i>f</i> | <i>af</i> | <i>bf</i> | | | | | |
| <i>H</i> | <i>de</i> | <i>ade</i> | | <i>cde</i> | | | | |

74

Extraction Rectangle Covering

- Number literals before - Number of literals after

$$V(R', C') = \sum_{i \in R, j \in C} v_{ij} - \sum_{i \in R'} w_i^r - \sum_{j \in C'} w_j^c$$

v_{ij} : Number of literals of cube m_{ij}

w_i^r : (Number of literals of the cube associated with row i) + 1

w_j^c : Number of literals of the cube associated with column j

- For prior example

- $V = 20 - 10 - 2 = 8$

| | | <i>a</i> | <i>b</i> | <i>c</i> | <i>ce</i> | <i>de</i> | <i>f</i> | <i>g</i> |
|--------------|-----------|------------|------------|------------|------------|------------|-----------|-----------|
| <i>F</i> | <i>a</i> | | | | | <i>ade</i> | <i>af</i> | <i>ag</i> |
| <i>F</i> | <i>b</i> | | | | | <i>bde</i> | <i>bf</i> | |
| <i>F</i> | <i>de</i> | <i>ade</i> | <i>bde</i> | <i>cde</i> | | | | |
| <i>F</i> | <i>f</i> | <i>af</i> | <i>bf</i> | | | | | |
| <i>M = F</i> | <i>c</i> | | | | | <i>cde</i> | | <i>cg</i> |
| <i>F</i> | <i>g</i> | <i>ag</i> | | <i>cg</i> | | | | |
| <i>G</i> | <i>a</i> | | | | <i>ace</i> | | <i>af</i> | |
| <i>G</i> | <i>b</i> | | | | <i>bce</i> | | <i>bf</i> | |
| <i>G</i> | <i>ce</i> | <i>ace</i> | <i>bce</i> | | | | | |
| <i>G</i> | <i>f</i> | <i>af</i> | <i>bf</i> | | | | | |
| <i>H</i> | <i>de</i> | <i>ade</i> | | <i>cde</i> | | | | |

75

Extraction Rectangle Covering

- Pseudo Boolean Division

- Idea: consider entries in covering matrix that are don't cares

- overlap of rectangles ($a+a = a$)

- product that cancel each other out ($a \cdot a' = 0$)

- Example:

$$F = ab' + ac' + a'b + a'c + bc' + b'$$

| | | <i>a</i> | <i>b</i> | <i>c</i> | <i>a'</i> | <i>b'</i> | <i>c'</i> |
|--------------|-----------|------------|------------|------------|------------|------------|------------|
| <i>F</i> | <i>a</i> | | | | * | <i>ab'</i> | <i>ac'</i> |
| <i>F</i> | <i>b</i> | | | | <i>a'b</i> | * | <i>bc'</i> |
| <i>M = F</i> | <i>c</i> | | | | <i>a'c</i> | <i>b'c</i> | * |
| <i>F</i> | <i>a'</i> | * | <i>a'b</i> | <i>a'c</i> | | | |
| <i>F</i> | <i>b'</i> | <i>ab'</i> | * | <i>b'c</i> | | | |
| <i>F</i> | <i>c'</i> | <i>ac'</i> | <i>bc'</i> | * | | | |

Result:

$$X = a' + b' + c'$$

$$F = ax + bx + cx$$

76

Fast Kernel Computation

- Non-robustness of kernel extraction
 - Recomputation of kernels after every substitution: expensive
 - Some functions may have many kernels (e.g. symmetric functions)
- Cannot measure if kernel can be used as complemented node
- Solution: compute only subset of kernels:
 - Two-cube “kernel” extraction [Rajski et al '90]
 - Objects:
 - 2-cube divisors
 - 2-literal cube divisors
 - Example: $f = abd + a'b'd + a'cd$
 - $ab + a'b'$, $b' + c$ and $ab + a'c$ are 2-cube divisors.
 - $a'd$ is a 2-literal cube divisor.

77

Fast Kernel Computation

- Properties of fast divisor (kernel) extraction:
 - $O(n^2)$ number of 2-cube divisors in an n -cube Boolean expression
 - Concurrent extraction of 2-cube divisors and 2-literal cube divisors
 - Handle divisor and complemented divisor simultaneously
- Example:
 - $f = abd + a'b'd + a'cd$
 - $k = ab + a'b'$, $k' = ab' + a'b$ (both 2-cube divisors)
 - $j = ab + a'c$, $j' = ab' + a'c'$ (both 2-cube divisors)
 - $c = ab$ (2-literal cube), $c' = a' + b'$ (2-cube divisor)

78

Fast Kernel Computation

□ Generating all two cube divisors

$$F = \{c_i\}$$

$$D(F) = \{d \mid d = \text{make_cube_free}(c_i + c_j)\}$$

- c_i, c_j are any pair of cubes of cubes in F
 - I.e., take all pairs of cubes in F and makes them cube-free
- Divisor generation is $O(n^2)$, where n = number of cubes in F

□ Example:

$$F = axe + ag + bcxe + bcg$$

$$\text{make_cube_free}(c_i + c_j) = \{xe + g, a + bc, axe + bcg, ag + bcxe\}$$

- **Note:** Function F is made into an algebraic expression before generating double-cube divisors
- Not all 2-cube divisors are kernels (why?)

79

Fast Kernel Computation

□ Key results of 2-cube divisors

Theorem: Expressions F and G have a common multiple-cube divisors **if and only if** $D(F) \cap D(G) \neq \emptyset$

Proof:

If:

If $D(F) \cap D(G) \neq \emptyset$ then $\exists d \in D(F) \cap D(G)$ which is a double-cube divisor of F and G. d is a multiple-cube divisor of F and of G.

Only if:

Suppose $C = \{c_1, c_2, \dots, c_m\}$ is a multiple-cube divisor of F and of G. Take any $e = (c_i + c_j)$. If e is cube-free, then $e \in D(F) \cap D(G)$. If e is not cube-free, then let $d = \text{make_cube_free}(c_i + c_j)$. d has 2 cubes since F and G are algebraic expressions. Hence $d \in D(F) \cap D(G)$.

80

Fast Kernel Computation

□ Example:

Suppose that $C = ab + ac + f$ is a multiple divisor of F and G

If $e = ac + f$, e is cube-free and $e \in D(F) \cap D(G)$

If $e = ab + ac$, $d = \{b + c\} \in D(F) \cap D(G)$

As a result of the Theorem, all multiple-cube divisors can be “discovered” by using just double-cube divisors

81

Fast Kernel Computation

□ Algorithm:

- Generate and store all 2-cube kernels (2-literal cubes) and recognize complement divisors
- Find the best 2-cube kernel or 2-literal cube divisor at each stage and extract it
- Update 2-cube divisor (2-literal cubes) set after extraction
- Iterate extraction of divisors until no more improvement

□ Results:

- Much faster
- Quality as good as that of kernel extraction

82

Boolean Division

□ What's wrong with algebraic division?

- Divisor and quotient are orthogonal!

- Better factored form might be:

$$(g_1 + g_2 + \dots + g_n) (d_1 + d_2 + \dots + d_m)$$

- g_i and d_j may share same literals

- redundant product literals

- Example

$$abe+ace+abd+cd / (ae+d) = \emptyset$$

$$\text{But: } aabe+ace+abd+cd / (ae+d) = (ab+c)$$

- g_i and d_j may share opposite literals

- product terms are non-existing

- Example

$$a'b+ac+bc / (a'+c) = \emptyset$$

$$\text{But: } a'a+a'b+ac+bc / (a'+c) = (a+b)$$

83

Boolean Division

□ Definition:

g is a **Boolean divisor** of f if h and r exist such that $f = gh + r$, $gh \neq 0$

g is said to be a **factor** of f if, in addition, $r = 0$, i.e., $f = gh$

- h is called the **quotient**

- r is called the **remainder**

- h and r may **not** be unique

84

Boolean Division

□ Theorem:

A logic function g is a **Boolean factor** of a logic function f if and only if $f \subseteq g$ (i.e. $fg' = 0$, i.e. $g' \subseteq f'$)

85

Boolean Division

Proof:

(\Rightarrow) g is a Boolean factor of f . Then $\exists h$ such that $f = gh$;
Hence, $f \subseteq g$ (as well as h).

(\Leftarrow) $f \subseteq g \Rightarrow f = gf = g(f + r) = gh$. (Here r is any function $r \subseteq g'$.)

□ Note:

- $h = f$ works fine for the proof
- Given f and g , h is not unique
- To get a small h is the same as to get a small $f + r$. Since $rg = 0$, this is the same as minimizing (simplifying) f with $DC = g'$.

86

Boolean Division

□ Theorem:

g is a Boolean divisor of f if and only if $fg \neq 0$

87

Boolean Division

Proof:

(\Rightarrow) $f = gh + r$, $gh \neq 0 \Rightarrow fg = gh + gr$. Since $gh \neq 0$, $fg \neq 0$.

(\Leftarrow) Assume that $fg \neq 0$. $f = fg + fg' = g(f + k) + fg'$. (Here $k \subseteq g'$.)

Then $f = gh + r$, with $h = f + k$, $r = fg'$. Since $gh = fg \neq 0$, then $gh \neq 0$.

□ Note:

- f has many divisors. We are looking for some g such that $f = gh + r$, where g, h, r are simple functions. (simplify f with DC = g')

88

Boolean Division

Incomplete Specified Function

□ $F = (f, d, r)$

□ Definition:

A completely specified logic function g is a **Boolean divisor of F** if there exist h, e (completely specified) such that

$$f \subseteq gh + e \subseteq f + d$$

and $gh \not\subseteq d$.

□ Definition:

g is a **Boolean factor of F** if there exists h such that

$$f \subseteq gh \subseteq f + d$$

89

Boolean Division

Incomplete Specified Function

□ Lemma:

$f \subseteq g$ if and only if g is a Boolean factor of F .

Proof:

(\Rightarrow) Assume that $f \subseteq g$. Let $h = f + k$ where $kg \subseteq d$.

Then $hg = (f + k)g \subseteq (f + d)$.

Since $f \subseteq g$, $fg = f$ and thus $f \subseteq (f + k)g = gh$.

Thus

$$f \subseteq (f + k)g \subseteq f + d$$

(\Leftarrow) Assume that $f = gh$.

Suppose \exists minterm m such that $f(m) = 1$ but $g(m) = 0$.

Then $f(m) = 1$ but $g(m)h(m) = 0$ implying that $f \not\subseteq gh$.

Thus $f(m) = 1$ implies $g(m) = 1$, i.e. $f \subseteq g$

□ Note:

■ Since $kg \subseteq d$, $k \subseteq (d + g')$. Hence obtain $h = f + k$ by simplifying f with $DC = (d + g')$.

90

Boolean Division

Incomplete Specified Function

□ Lemma:

$fg \neq 0$ if and only if g is a Boolean divisor of F .

Proof:

(\Rightarrow) Assume $fg \neq 0$.

Let $fg \subseteq h \subseteq (f + d + g')$ and $fg' \subseteq e \subseteq (f + d)$.

Then $f = fg + fg' \subseteq gh + e \subseteq g(f + d + g') + f + d = f + d$

Also, $0 \neq fg \subseteq gh \rightarrow ghf \neq 0$.

Now $gh \not\subseteq d$, since otherwise $ghf = 0$ (since $fd = 0$),
verifying the conditions of Boolean division.

(\Leftarrow) Assume that g is a Boolean divisor.

Then $\exists h$ such that $gh \not\subseteq d$ and

$f \subseteq gh + e \subseteq f + d$

Since $gh = (ghf + ghd) \not\subseteq d$, then $fgh \neq 0$ implying that $fg \neq 0$.

91

Boolean Division

Incomplete Specified Function

□ Recipe for Boolean division:

($f \subseteq gh + e \subseteq f + d$)

■ Choose g such that $fg \neq 0$

■ Simplify fg with DC = $(d + g')$ to get h

■ Simplify fg' with DC = $(d + fg)$ to get e (could use DC = $d + gh$)

□ $fg \subseteq h \subseteq f + d + g'$

$fg' \subseteq e \subseteq fg' + d + fg = f + d$

92

Boolean Division

- Given $F = (f,d,r)$, write a cover for F in the form $gh + e$ where h and e are minimal in some sense

Algorithm:

- Create a new variable x to “represent” g
- Form the don't care set ($\tilde{d} = xg' + x'g$)
(Since $x = g$ we don't care if $x \neq g$)
- Minimize $(f\tilde{d}', d + \tilde{d}, r\tilde{d}')$ to get \tilde{f}
- Return $(h = \tilde{f}/x, e)$ where e is the remainder of \tilde{f}
(These are simply the terms not containing x)
- f/x denote weak algebraic division

93

Boolean Division

- Note that $(f\tilde{d}', d + \tilde{d}, r\tilde{d}')$ is a partition. We can use ESPRESSO to minimize it, but the objective there is to minimize the number of cubes - not completely appropriate.

- Example:
 $f = a + bc$
 $g = a + b$

$$\tilde{d} = xa'b' + x'(a+b) \text{ where } x = g = (a+b)$$

- Minimize $(a + bc)\tilde{d}' = (a + bc)(x'a'b' + x(a+b)) = xa + xbc$
with $DC = xa'b' + x'(a+b)$
- A minimum cover is $a + bc$ but it does not use x or x' !
- Force x in the cover. This yields $f = a + xc = a + (a+b)c$.

Heuristic:

Find answer with x in it and which also uses the least variables (or literals)

94

Boolean Division

Assume F is a cover for $\mathfrak{S} = (f,d,r)$ and D is a cover for d .

First Algorithm:

```
Algorithm Boolean_Divide1(F,D,G) {
  D1 = D + xG' + x'G           // (don't care)
  F1 = FD1'                   // (care on-set)
  R1 = (F1 + D1)' = F1'D1' = F'D1' // (care off-set)
  F2 = remove x' from F1       // positive substitution only
  F3 = MIN_LITERAL(F2, R1, x) // Filter for Espresso
           // (minimum literal support including x)
  F4 = ESPRESSO(F3,D1,R1)
  H = F4/x                       // (quotient)
  E = F4 - {xH}                   // (remainder)
  return (HG+E)
}
```

95

Boolean Division

Assume F is a cover for $\mathfrak{S} = (f,d,r)$ and D is a cover for d .

Second Algorithm:

```
Algorithm Boolean_Divide2(F,D,G) {
  D1 = D + xG' + x'G           // (don't care)
  F1 = FD1'                   // (on-set)
  R1 = (F1 + D1)' = F1'D1' = F'D1' // (off-set)
  // F2 = remove x' from F1 (difference to first alg.)
  F3 = MIN_LITERAL(F2, R1, x, x') // Filter for Espresso
           // (minimum literal support including x)
  F4 = ESPRESSO(F3,D1,R1)
  H1 = F4/x                       // (first quotient)
  H0 = F4/x'                       // (first quotient)
  E = F4 - ({xH1} + {x'H0}) // (remainder)
  return (GH1+G'H0+E)
}
```

96

Boolean Division

Minimal Literal Support

Support minimization (MINVAR)

Given:

$$\mathfrak{S} = (f, d, r)$$

$$F = \{c^1, c^2, \dots, c^k\} \quad (\text{a cover of } \mathfrak{S})$$

$$R = \{r^1, r^2, \dots, r^m\} \quad (\text{a cover of } r)$$

1. Construct blocking matrix B^i for each c^i
2. Form "super" blocking matrix B
3. Find a minimum cover S of B ,

$$B = \begin{bmatrix} B^1 \\ B^2 \\ \vdots \\ B^k \end{bmatrix}$$

$$S = \{j_1, j_2, \dots, j_v\}.$$

4. Modify $\tilde{F} \leftarrow \{\tilde{c}^1, \tilde{c}^2, \dots, \tilde{c}^k\}$ where

$$(\tilde{c}^i)_j = \begin{cases} (\tilde{c}^i)_j & \text{if } j \in S \\ \{0, 1\} = 2 & \text{otherwise} \end{cases}$$

97

Boolean Division

Minimal Literal Support

Given:

$$\mathfrak{S} = (f, d, r)$$

$$F = \{c^1, c^2, \dots, c^k\} \quad (\text{a cover of } \mathfrak{S})$$

$$R = \{r^1, r^2, \dots, r^m\} \quad (\text{a cover of } r)$$

n : number of variables

Literal Blocking Matrix:

$$(\hat{B}^i)_{q,j} = \begin{cases} 1 & \text{if } v_j \in c^i \text{ and } v_j \in r^q \\ 0 & \text{otherwise} \end{cases}$$

$$(\hat{B}^i)_{q,j+n} = \begin{cases} 1 & \text{if } v_j \in c^i \text{ and } v_j \in r^q \\ 0 & \text{otherwise} \end{cases}$$

Example:

$$c^i = ad'e', \quad r^q = a'ce$$

$$\hat{B}_q^i = \begin{matrix} abcde a'b'c'd'e' \\ 1000000001 \end{matrix}$$

98

Boolean Division

Minimal Literal Support

□ Example (literal blocking matrix)

on-set cube: $c^1 = ab'd$

off-set: $r = a'b'd' + abd' + acd' + bcd + c'd'$

| | a | b | c | d | a' | b' | c' | d' |
|--------|---|---|---|---|----|----|----|----|
| a'b'd' | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| abd' | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 |
| acd' | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| bcd | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| c'd' | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |

■ Minimum column cover $\{d, b'\}$

■ Thus $b'd$ is the maximum prime covering $ab'd$

■ Note:

For one cube, minimum literal support is the same as minimum variable support

99

Boolean Division

□ Example

$F = a + bc$

Algebraic division: $F/(a + b) = 0$

Boolean division: $F \div (a + b) = a + c$

1. Let $x = a + b$

2. Generate don't care set: $D_1 = x'(a + b) + xa'b'$.

3. Generate care on-set:

□ $F_1 = F \cap D_1' = (a + bc)(xa + xb + x'a'b') = ax + bcx$.

□ Let $C = \{c^1 = ax, c^2 = bcx\}$

4. Generate care off-set:

□ $R_1 = F'D_1' = (a'b' + a'c')(xa + xb + x'a'b') = a'bc'x + a'b'x'$.

□ Let $R = \{r^1 = a'bc'x, r^2 = a'b'x'\}$.

5. Form super-variable blocking matrix using column order (a, b, c, x) , with a', b', c', x' omitted.

$$B = \begin{bmatrix} B^1 \\ B^2 \end{bmatrix} = \begin{bmatrix} 1000 \\ 1001 \\ 0010 \\ 0101 \end{bmatrix}$$

100

Boolean Division

□ Example (cont'd)

6. Find minimum column cover = {a, c, x}
7. Eliminate in F_1 all variables associated with b
So $F_1 = ax + bcx = ax + cx = x(a + c)$
8. Simplifying (applying expand, irredundant on F_1), we get $F_1 = a + xc$
9. Thus quotient = $F_1/x = c$, remainder = a
10. $F = a + bc = a + cx = a + c(a + b)$

It is important that x is forced in the cover!

$$B = \begin{bmatrix} B^1 \\ B^2 \end{bmatrix} = \begin{array}{c} \text{a b c x} \\ \begin{bmatrix} 1000 \\ 1001 \\ 0010 \\ 0101 \end{bmatrix} \end{array}$$
