Introduction
to
Logic Synthesis with ABC

Alan Mishchenko

UC Berkeley

Overview

- **(1) Problems in logic synthesis**
  - Representations and computations
- **(2) And-Inverter Graphs (AIGs)**
  - The foundation of innovative synthesis
- **(3) AIG-based solutions**
  - Synthesis, mapping, verification
- **(4) Introduction to ABC**
  - Differences, fundamentals, programming
- **(5) Programming assignment**

(1) Problems in Synthesis

- ## What are the objects to be "synthesized"?
  - Logic structures
  - Boolean functions (with or without don't-cares)
  - State machines, relations, sets, etc.
- ## How to represent them efficiently?
  - Depends on the task to be solved
  - Depends on the size of an object
- ## How to create, transform, minimize the representations?
  - Multi-level logic synthesis
  - Technology mapping
- ## How to verify the correctness of the design?
  - Gate-level equivalence checking
  - Property checking
  - Etc.

3

Terminology

- ## Logic function (e.g. $F = ab+cd$)
  - Variables (e.g. b)
  - Minterms (e.g. $ab\bar{c}d$)
  - Cube (e.g. ab)
- ## Logic network
  - Primary inputs/outputs
  - Logic nodes
  - Fanins/fanouts
  - Transitive fanin/fanout cone
  - Cut and window (defined later)

Primary outputs

TFO

Fanouts

Fanins

TFI

Primary inputs
4

Logic (Boolean) Function

- Completely specified logic function

ab / cd

cd \ ab	00	01	11	10
00	0	0	1	0
01	0	0	1	0
11	1	1	1	1
10	0	0	1	0

- Incompletely specified logic function

ab / cd

cd \ ab	00	01	11	10
00	0	0	1	0
01	0	–	–	–
11	1	1	1	–
10	0	0	1	0

On-set

	00	01	11	10
00	0	0	1	0
01	0	0	0	0
11	1	1	1	0
10	0	0	1	0

Off-set

	00	01	11	10
00	1	1	0	1
01	1	0	0	0
11	0	0	0	0
10	1	1	0	1

DC-set

	00	01	11	10
00	0	0	0	0
01	0	1	1	1
11	0	0	0	1
10	0	0	0	0

5

Relations

- Relation (a1,a2) → (b1,b2)
  - (0,0) → (0,0)
  - (0,1) → (1,0)(0,1)
  - (1,0) → (1,1)
  - (1,1) → (1,0)

- FSM

Characteristic function

a1 a2

b1 b2 \ a1 a2	00	01	11	10
00	1	0	0	0
01	0	1	0	0
11	0	0	0	1
10	0	1	1	0
Current state

| Next state \	00	01	11	10
00	1	1	–	0
01	1	1	–	1
11	–	–	–	–
10	1	0	–	0

6

Representation Zoo

Find each of these representations?
- Truth table (TT)
- Sum-of-products (SOP)
- Product-of-sums (POS)
- Binary decision diagram (BDD)
- And-inverter graph (AIG)
- Logic network (LN)

F = ab+cd

F = (a+c)(a+d)(b+c)(b+d)

abcd	F
0000	0
0001	0
0010	0
0011	1
0100	0
0101	0
0110	0
0111	1
1000	0
1001	0
1010	0
1011	1
1100	1
1101	1
1110	1
1111	1

Representation Overview

- **TT are the natural representation of logic functions**
  - Not practical for large functions
  - Still good for functions up to 16 variables
- **SOP is widely used in synthesis tools since 1980's**
  - More compact than TT, but not canonical
  - Can be efficiently minimized (SOP minimization by Espresso, ISOP computation) and translated into multi-level forms (algebraic factoring)
- **BDD is a useful representation discovered around 1986**
  - Canonical (for a given function, there is only one BDD)
  - Very good, but only if (a) it can be constructed, (b) it is not too large
  - Unreliable (non-robust) for many industrial circuits
- **AIG is an up-and-coming representation!**
  - Compact, easy to construct, can be made "canonical" using a SAT solver
  - Unifies the synthesis/mapping/verification flow
  - The main reason to give this talk ☺

Historical Perspective

Problem Size

AIG
CNF

TT

SOP

BDD

1950-1970   1980   1990   2000   Time

What Representation to Use?

- For small functions (up to 16 inputs)
  - TT works the best (local transforms, decomposition, factoring, etc.)
- For medium-sized functions (16-100 inputs)
  - In some cases, BDDs are still used (reachability analysis)
  - Typically, it is better to represent as AIGs
    - Translate AIG into CNF and use SAT solver for logic manipulation
      - Sometimes need interpolation or SAT assignment enumeration
- For large industrial circuits (>100 inputs, >10,000 gates)
  - Traditional LN representation is not efficient
  - AIGs work remarkably well
    - Lead to efficient synthesis
    - Are a natural representation for technology mapping
    - Easy to translate into CNF for SAT solving
    - Etc.

What are Typical Transformations?

- Typical transformations of representations
    - For SOP, minimize cubes/literals
    - For BDD, minimize nodes/width
    - For AIG, restructure, minimize nodes/levels
    - For LN, restructure, minimize area/delay

Algorithmic Paradigms

- Divide-and-conquer
    - Traversal, windowing, cut computation
- Guess-and-check
    - Bit-wise simulation
- Reason-and-prove
    - Boolean satisfiability

Traversal

- **Traversal** is visiting nodes in the network in some order

- **Topological order** visits nodes from PIs to POs
  - Each node is visited after its fanins are visited

- **Reverse topological order** visits nodes from POs to PIs
  - Each node is visited after its fanouts are visited

Primary outputs

Primary inputs
Traversal in a topological order

13

Windowing

- **Definition**
  - A **window** for a node is the node's context, in which an operation is performed
- **A window includes**
  - **k** levels of the TFI
  - **m** levels of the TFO
  - all re-convergent paths between window PIs and window POs

Window POs

m = 3

Pivot node

k = 3

Window PIs
14

Structural Cuts in AIG

A **cut** of a node *n* is a set of nodes in transitive fan-in such that every path from the node to PIs is blocked by nodes in the cut.

A **k-feasible cut** means the size of the cut must be *k* or less.
The set {p, b, c} is a 3-feasible cut of node n. (It is also a 4-feasible cut.)

k-feasible cuts are important in FPGA mapping because the logic between root n and the cut nodes {p, b, c} can be replaced by a *k*-LUT

15

Cut Computation

{ {n}, {p, q}, {p, b, c}, {a, b, q}, {a, b, c} }
Computation is done bottom-up

{ {p}, {a, b} }   { {q}, {b, c} }

{ {a} }   { {b} }   { {c} }

k	Cuts per node
4	6
5	20
6	80
7	150

The set of cuts of a node is a 'cross product' of the sets of cuts of its children.
Any cut that is of size greater than *k* is discarded.

(P. Pan et al, FPGA '98; J. Cong et al, FPGA '99)   16

Bitwise Simulation

- Assign particular (or random) values at the primary inputs
  - Multiple simulation patterns are packed into 32- or 64-bit strings

- Perform bitwise simulation at each node
  - Nodes are ordered in a topological order

- Works well for AIG due to
  - The uniformity of AND-nodes
  - Speed of bitwise simulation
  - Topological ordering of memory used for simulation information
Boolean Satisfiability

- Given a CNF formula $\varphi(x)$, satisfiability problem is to prove that $\varphi(x) \equiv 0$, or to find a counter-example x' such that $\varphi(x') \equiv 1$

- Why this problem arises?
  - If CNF were a canonical representation (like BDD), it would be trivial to answer this question.
  - But CNF is not canonical. Moreover, CNF can be very redundant, so that a large formula is, in fact, equivalent to 0.
  - Looking for a satisfying assignment can be similar to searching for a needle in the hay-stack.
  - The problem may be even harder, if there is no needle there!

Example (Deriving CNF)

CNF

$(a + b + c)$

$(a + b + c')$

$(a' + b + c')$

$(a + c + d)$

$(a' + c + d)$

$(a' + c + d')$

$(b' + c' + d')$

$(b' + c' + d)$

ab

cd   00   01   11   10

00 | 0 | 0 | 0 | 0 |

01 | 0 | 1 | 0 | 0 |

11 | 0 | 0 | 0 | 0 |

10 | 0 | 0 | 0 | 0 |

Cube: bcd'

Clause: b' + c' + d

SAT Solver

- SAT solver types
  - CNF-based, circuit-based
  - Complete, incomplete
  - DPLL, saturation, etc.

- Applications in EDA
  - Verification
    - Equivalence checking
    - Model checking
  - Synthesis
    - Circuit restructuring
    - Decomposition
    - False path analysis
  - Routing

- A lot of magic is used to build an efficient SAT solver
  - Two literal clause watching
  - Conflict analysis with clause recording
  - Non-chronological backtracking
  - Variable ordering heuristics
  - Random restarts, etc

- The best SAT solver is MiniSAT (http://minisat.se/)
  - Efficient (won many competitions)
  - Simple (600 lines of code)
  - Easy to modify and extend
  - Integrated into ABC

Example (SAT Solving)

1. $(a + b + c)$
2. $(a + b + \neg c)$
3. $(\neg a + b + \neg c)$
4. $(a + c + d)$
5. $(\neg a + c + d)$
6. $(\neg a + c + \neg d)$
7. $(\neg b + \neg c + \neg d)$
8. $(\neg b + \neg c + d)$

---
(2) And-Inverter Graphs (AIG)

- Definition and examples
- Several simple tricks that make AIGs work
- Sequential AIGs
- Unifying representation
- A typical synthesis application: AIG rewriting

AIG Definition and Examples

AIG is a Boolean network composed of two-input ANDs and inverters.

$$F(a,b,c,d) = ab + d(ac'+bc)$$
6 nodes
4 levels

$$F(a,b,c,d) = ac'(b'd')' + c(a'd')' = ac'(b+d) + bc(a+d)$$
7 nodes
3 levels

Three Simple Tricks

- **Structural hashing**
  - Makes sure AIG is stored in a compact form
  - Is applied during AIG construction
    - Propagates constants
    - Makes each node structurally unique
- **Complemented edges**
  - Represents inverters as attributes on the edges
    - Leads to fast, uniform manipulation
    - Does not use memory for inverters
    - Increases logic sharing using DeMorgan's rule
- **Memory allocation**
  - Uses fixed amount of memory for each node
    - Can be done by a simple custom memory manager
    - Even dynamic fanout manipulation is supported!
  - Allocates memory for nodes in a topological order
    - Optimized for traversal in the same topological order
    - Small static memory footprint for many applications
  - Computes fanout information on demand

Without hashing

With hashing
Sequential AIGs

- Sequential networks have memory elements in addition to logic nodes
  - Memory elements are modeled as D-flip-flops
  - Initial state {0,1,x} is assumed to be given
- Several ways of representing sequential AIGs
  - Additional PIs and POs in the combinational AIG
  - Additional register nodes with sequential structural hashing
- Sequential synthesis (in particular, retiming) annotates registers with additional information
  - Takes into account register type and its clock domain

AIG: A Unifying Representation

- An underlying data structure for various computations
  - Rewriting, resubstitution, simulation, SAT sweeping, induction, etc. are based on the same AIG manager
- A unifying representation for the whole flow
  - Synthesis, mapping, verification use the same data structure
  - Allows multiple structures to be stored and used for mapping
- The main functional representation in ABC
  - A foundation of new logic synthesis

(3) AIG-Based Solutions

- Synthesis
- Mapping
- Verification

Design Flow
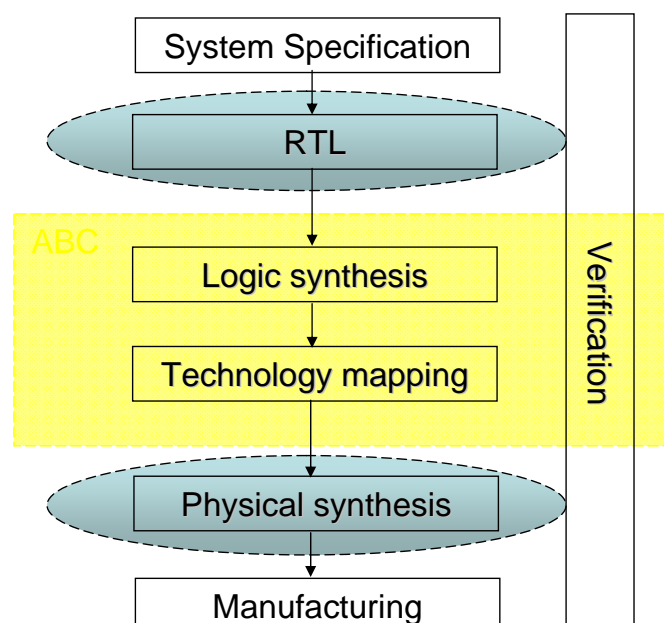

Combinational Synthesis

- **AIG rewriting** minimizes the number of AIG nodes without increasing the number of AIG levels

- Pre-computing AIG subgraphs
  - Consider function f = abc

Rewriting AIG subgraphs

Subgraph 1   Subgraph 2   Subgraph 3

Rewriting node A

Rewriting node B

In both cases 1 node is saved
29

AIG-Based Solutions (Synthesis)

- Restructures AIG or logic network by the following transforms
  - Algebraic balancing
  - Rewriting/refactoring/redecomposition
  - Resubstitution
  - Minimization with don't-cares, etc.

Synthesis

D1 → D2 → D3 → D4
Synthesis with choices

D1 → D2 → D3 → HAIG → D4
30

AIG-Based Solutions (Mapping)

Input: A Boolean network (And-Inverter Graph)

Output: A netlist of *K*-LUTs implementing AIG and optimizing some cost function

Technology Mapping

f

a   b   c   d   e

The subject graph

f

a b c d e
The mapped netlist

Formal Verification

- Equivalence checking
  - Takes two designs and makes a miter (AIG)
- Model checking *safety* properties
 - Takes design and property and makes a miter (AIG)
The goals are the same: to transform AIG until the output is proved constant 0

(ABC won model checking competitions in recent years)

Equivalence checking

D1   D2   → 0

Property checking

$\overline{p}$

D1   → 0

(4) Introduction to ABC

- Differences
- Fundamentals
- Programming

What Is Berkeley ABC?

- A system for logic synthesis and verification
  - Fast
  - Scalable
  - High quality results (industrial strength)
  - Exploits synergy between synthesis and verification
- A programming environment
  - Open-source
  - Evolving and improving over time

Existing Capabilities (2005-2008)

<div style="border:1px solid black">

Combinational logic synthesis
Fast, scalable, good quality

</div>

<div style="border:1px solid black">

Technology mapping with structural choices
Cut-based, heuristic, good area/delay, flexible

</div>

ABC

<div style="border:1px solid black">

Sequential verification
Integrated, interacts with synthesis

</div>

<div style="border:1px solid black">

Sequential synthesis
Innovative, scalable, verifiable
</div>

Screenshot

ABC vs. Other Tools

- Industrial
  - + well documented, fewer bugs
  - - black-box, push-button, no source code, often expensive
- SIS
  - + traditionally very popular
  - - data structures / algorithms outdated, weak sequential synthesis
- VIS
  - + very good implementation of BDD-based verification algorithms
  - - not meant for logic synthesis, does not feature the latest SAT-based implementations
- MVSIS
  - + allows for multi-valued and finite-automata manipulation
 - - not meant for binary synthesis, lacking recent implementations

37

# How Is ABC Different From SIS?

Boolean network in SIS   Equivalent AIG in ABC

AIG is a Boolean network of 2-input
AND nodes and inverters (dotted lines) 38

One AIG Node – Many Cuts

Combinational AIG

Different cuts for the same node

- Manipulating AIGs in ABC
  - Each node in an AIG has many cuts
  - Each cut is a different SIS node
  - No a priori fixed boundaries
- Implies that AIG manipulation with cuts is equivalent to working on *many* Boolean networks at the same time

---

Comparison of Two Syntheses

"Classical" synthesis

- Boolean network
- Network manipulation (algebraic)
  - Elimination
  - Factoring/Decomposition
  - Speedup
- Node minimization
  - Espresso
  - Don't cares computed using BDDs
  - Resubstitution
- Technology mapping
  - Tree based

ABC "contemporary" synthesis

- AIG network
- DAG-aware AIG rewriting (Boolean)
  - Several related algorithms
    - Rewriting
    - Refactoring
    - Balancing
    - Speedup
- Node minimization
  - Boolean decomposition
  - Don't cares computed using simulation and SAT
  - Resubstitution with don't cares
- Technology mapping
  - Cut based with choice nodes

Model Checking Competition

Cactus all Instances

Further Reading: ABC Tutorial

- For more information, please refer to

    - R. Brayton and A. Mishchenko, "ABC: An academic industrial-strength verification tool", Proc. CAV'10, Springer, LNCS 6174, pp. 24-40.

    - http://www.eecs.berkeley.edu/~alanmi/publications/2010/cav10_abc.pdf

Summary

- Introduced problems in logic synthesis
    - Representations and computations
- Described And-Inverter Graphs (AIGs)
    - The foundation of innovative synthesis
- Overviewed AIG-based solutions
    - Synthesis, mapping, verification
- Introduced ABC
    - Differences, fundamentals, programming

Assignment: Using ABC

- Referring to BLIF manual
  http://www.eecs.berkeley.edu/~alanmi/publications/other/blif.pdf, and
  create a BLIF file representing a 4-bit adder

- Perform the following sequence:
  - read the file into ABC (command "read")
  - check statistics (command "print_stats")
  - visualize the network structure (command "show")
  - convert to AIG (command "strash")
  - visualize the AIG (command "show")
  - convert to BDD (command "collapse")
  - visualize the BDD (command "show_bdd")

- Comment 1: For commands "show" and "show_bdd" to work, please
  download the binary of software "dot" from GraphViz webpage and put it in
  the same directory as the ABC binary or anywhere else in the path:
  http://www.graphviz.org

- Comment 2: Make sure GSview and Ghostscript are installed on your
  computer. http://pages.cs.wisc.edu/~ghost/gsview/

Assignment: Programming ABC

- Write a procedure in ABC environment to iterate
  over the nodes of a given AIG, perform bitwise
  simulation with respect to a set of input patterns,
  and output the output patterns. Integrate this
  procedure into ABC, so that running command
  "test" would invoke your code, and print the
  result.

Programming Help

- Example of code to iterate over the objects

```
void Abc_NtkCleanCopy( Abc_Ntk_t * pNtk )
{
    Abc_Obj_t * pObj;
    int i;
    Abc_NtkForEachObj( pNtk, pObj, i )
          pObj->pCopy = NULL;
}
```
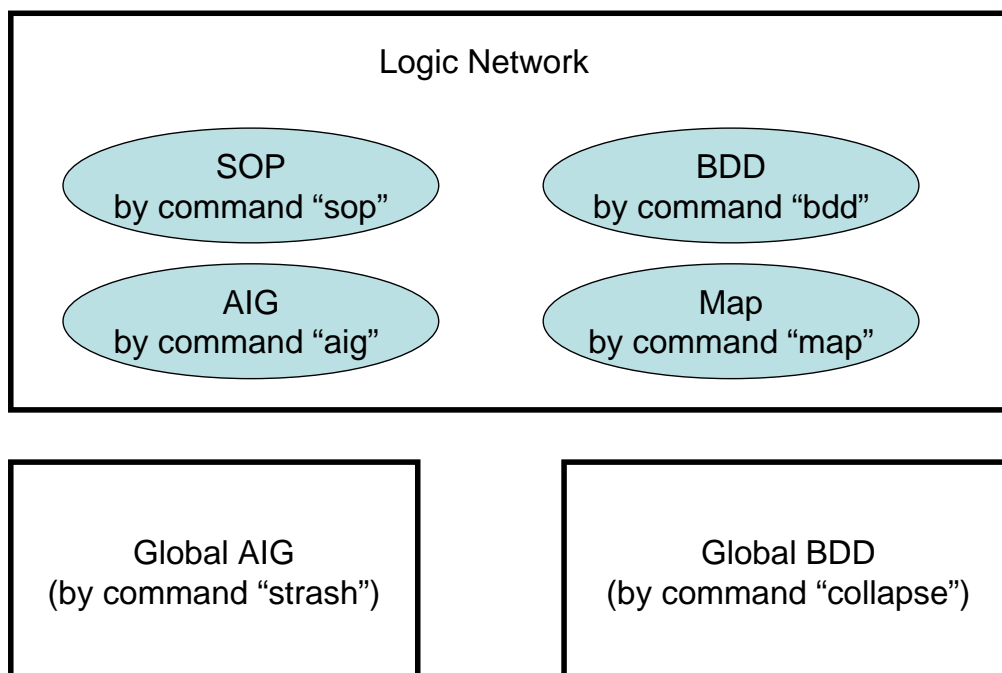

- Example of code to create new command "test"

  Call the new procedure (say, Abc_NtkPrintObjs) from Abc_CommandTest() in file "abc\src\base\abci\abc.c"

  `Abc_NtkPrintObjs( pNtk );`

ABC Network Data Types

Logic Network

SOP
by command "sop"

BDD
by command "bdd"

AIG
by command "aig"

Map
by command "map"

Global AIG
(by command "strash")

Global BDD
(by command "collapse")
